Communicable Diseases Intelligence (CDI) is a peer-reviewed scientific journal published by the Office of Health Protection, Department of Health and Aged Care. The journal aims to disseminate information on the epidemiology, surveillance, prevention and control of communicable diseases of relevance to Australia.

COVID-19 Australia: Epidemiology Report 76

Reporting period ending 2 July 2023

COVID-19 Epidemiology and Surveillance Team

Summary

Four-week reporting period (5 June – 2 July 2023)

Case definitions for confirmed and probable cases are in accordance with the coronavirus disease 2019 (COVID-19) Series of National Guidelines for Public Health Units (SoNG).

Trends – Nationally, following the peak of the fifth Omicron wave in the week ending 21 May 2023, there has been a decrease in COVID-19 case notifications. In the four-week period 5 June – 2 July 2023, there were 22,721 confirmed and 40,616 probable cases of COVID-19 reported in Australia to the National Notifiable Diseases Surveillance System (NNDSS). In the most recent reporting fortnight, a total of 23,827 confirmed and probable cases were notified (an average of 1,702 cases per day), compared with 39,510 in the previous fortnight (an average of 2,822 cases per day).

Age group – Since late May 2023, notification rates have decreased among all age groups. In the current reporting period, 5 June – 2 July 2023, the highest notification rate was observed among adults aged 90 years and over, whilst the lowest rates were among young people and children aged 19 years or less. For the entire Omicron wave to date (15 December 2021 – 4 June 2023), the highest notification rate has been in adults aged 20 to 29 years.

Aboriginal and Torres Strait Islander people – In the reporting period 5 June – 2 July 2023, there were 1,993 new cases notified in Aboriginal and Torres Strait Islander people. In the Omicron wave to date (15 December 2021 – 2 July 2023), there have been 418,311 cases notified among Aboriginal and Torres Strait Islander people, representing 3.7% of all cases (418,311/11,291,678) during this period.

Severity – Since early June 2023, there has been a decrease in the number of cases with severe illness (defined as those admitted to ICU or died). The overall crude case fatality rate from the start of the Omicron wave to date is 0.18%, which is lower than the crude rate during the Delta wave (0.71%). Since the start of the pandemic to 2 July 2023, there have been 182 cases of paediatric inflammatory multisystem syndrome - temporally associated with SARS-CoV-2 (PIMS-TS) reported to the Paediatric Active Enhanced Disease Surveillance network (PAEDS), with three new cases reported in the last four weeks, two new cases from the previous reporting period, and a total of 16 cases reported since the start of 2023.

Virology – For samples collected in the four-week period 5 June – 2 July 2023, all 1,314 samples were assigned against Omicron or recombinants consisting of Omicron lineages. There is currently significant diversity in the range of sub- and sub-sub-lineages circulating within Australia.

During the reporting period, more than 200 unique lineages have been identified. In this reporting period, recombinant lineages represented the majority (88.5%) of sequences collected and 11.5% belonged to BA.2.75 sub-lineages.

Acute respiratory illness – Based on self-reported FluTracking data, there has been an overall increase in the prevalence of both ‘fever and cough’ and ‘runny nose and sore throat’ symptoms in the community since late January 2023. Over the current period, the rate of ‘fever and cough’ has decreased and remains lower than the rates observed during the same period in 2022. The rate of ‘runny nose and sore throat’ symptoms has increased in early July 2023, with rates of this symptom profile now similar to those observed in 2022 for the same period.

International situation – According to the World Health Organization (WHO), cumulative global COVID-19 cases stood at over 767 million COVID-19 cases, with over 6.9 million deaths as of 2 July 2023. For the South-East Asia and Western Pacific regions combined, there were 613,455 new cases and 1,188 deaths in the four-week period to 2 July 2023. A proportional decrease in new cases and deaths was observed in the South-East Asia (change in cases: -69% & deaths: -55%) and the Western Pacific regions (change in cases: -36% & deaths: -41%) compared with the previous four weeks. In total, since the start of the pandemic, approximately 265 million cases and over 1.2 million deaths have been reported in the two regions.

Keywords: SARS-CoV-2; novel coronavirus; 2019-nCoV; coronavirus disease 2019; COVID-19; acute respiratory disease; epidemiology; Australia

This reporting period covers the four-week period of 5 June – 2 July 2023. Within this period, data for each week is compared. The previous reporting period was the preceding four weeks (8 May – 4 June 2023).¹ The focus of this report is on the epidemiological situation in Australia since the beginning of the Omicron wave. For the purposes of this report, 15 December 2021 is used as a proxy for the beginning of this wave. This date was chosen as from this date onwards, most sequenced strains from cases were Omicron. Readers are encouraged to consult prior reports in this series for information on the epidemiology of coronavirus disease 2019 (COVID-19) in Australia.

Methods of data analysis in these reports have periodically changed over the course of this reporting series to date. Please refer to the Technical Supplement for details of such changes, and for definitions of terminology.²

From Report #72 onward, and unless specified otherwise, all data from the National Notifiable Diseases Surveillance System (NNDSS) have

been extracted using ‘diagnosis date’ rather than ‘notification received date’ (see the Technical Supplement for definitions). Due to COVID-19 reporting changes in several states and territories, the use of ‘diagnosis date’ now provides a more consistent and accurate method for describing transmission trends in Australia.

The case data provided includes both confirmed cases and probable cases reported to the NNDSS, as defined in accordance with the COVID-19 series of national guidelines (SoNG).³ For the purposes of this report, only probable cases from 5 January 2022 are included. Since 1 July 2023, Victoria has ceased collecting and reporting data on probable COVID-19 cases.

From Report #71 onward, population data for Aboriginal and Torres Strait Islander people was updated (from 2016) and is now based on Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at 2021. There has been an increase of 185,600 Aboriginal and Torres Strait Islander people (23.2%) since the

previous ERP (June 2016). Therefore, notification rate comparisons with reports prior to #71 should be undertaken with caution.

Due to the dynamic nature of data in the NNDSS, numbers may be subject to revision and may vary from numbers previously reported and from case notifications released by states and territories.

Background and data sources

See the Technical Supplement for general information on COVID-19 including modes of transmission, common symptoms, and severity.²

Activity

COVID-19 trends (NNDSS)

Cumulatively, from the beginning of the pandemic to 2 July 2023, jurisdictions within Australia have reported 11,535,116 COVID-19 cases to the NNDSS. Nationally, following the peak of the fifth Omicron wave in the week ending 21 May 2023, there has been a decrease in COVID-19 case notifications (Figure 1).

In the four-week period 5 June – 2 July 2023, there were 22,721 confirmed and 40,616 probable cases of COVID-19 reported in Australia to the NNDSS (Table 1). In the most recent

b Population data based on Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at June 2022.

reporting fortnight, a total of 23,827 confirmed and probable cases were notified (an average of 1,702 cases per day), compared to 39,510 in the previous fortnight (an average of 2,822 cases per day).

Since the emergence of the Omicron variant in Australia, there have been five distinct waves of transmission, defined by the predominant Omicron subvariant circulating (Figure 1). The first wave, driven by the BA.1 subvariant, occurred from mid-December 2021 to February 2022, with a peak in cases observed in early January 2022. From March 2022, the BA.2 subvariant was the predominant strain; in this second Omicron wave, there was a primary peak in early April and a secondary peak in late May 2022 (Figure 1). In early July 2022, BA.5 (including sub-lineages) became the predominant subvariant detected in Australia, driving a third wave of transmission which peaked in the week ending 24 July 2022. A fourth wave of transmission commenced in late October 2022, driven by a combination of existing and newly emerging Omicron subvariants. This wave peaked during the week ending 11 December 2022 (Figure 1).

As the pandemic has progressed, the proportion of cases reported through surveillance mechanisms has decreased and there are many different sub-lineages of virus circulating simultaneously. Additionally, increases in other measures of disease activity, such as the numbers of people admitted to hospital, ICU or having died often lag weeks behind increases in infections in the community. This has made assessing the start of a new wave more complex, with the determination often now only possible several weeks after the wave has commenced.

While the patterns of case notifications have changed compared to previous waves, nationally, there has been an increasing trend in hospitalisations from mid-March 2023, reflecting the start of a fifth Omicron wave of COVID-19 transmission. During this wave, case numbers and severity indicators have remained lower than observed in previous Omicron waves.

Similar to the fourth Omicron wave, this fifth wave is driven by a combination of existing and newly emerging recombinant Omicron subvariants.

Due to a reduction in case ascertainment in all jurisdictions, including changes in testing and reporting requirements, reported case numbers are an underestimate of disease incidence in the community.

Demographic features

(NNDSS)

Since late May 2023, notification rates have decreased across all age groups (Figure 2). The highest notification rates continue to be among adults aged 60 years and over (Figure 2). In the current reporting period, 5 June – 2 July 2023, the highest notification rate was observed among adults aged 90 years and over, whilst the lowest rates were among young people and children aged 19 years or less (Appendix A, Table A.1). For the entire Omicron wave to date (15 December 2021 – 2 July 2023), the highest notification rate has been in adults aged 20 to 29 years (Appendix A, Table A.1). For this age group, the weekly notification rate peaked in the week ending 9 January 2022 at approximately 5,800 cases per 100,00 population (not depicted).

Aboriginal and Torres Strait Islander persons

(NNDSS)

Overall, since the start of the pandemic, Indigenous status is unknown for approximately 13.0% of COVID-19 cases in NNDSS. Therefore, the number of cases classified as Aboriginal and Torres Strait Islander people is likely an under-representation. During the reporting period, there were 1,993 new cases notified among Aboriginal and Torres Strait Islander people (Table 2). In the Omicron wave to date (15 December 2021 – 2 July 2023), there have been 418,311 cases notified among Aboriginal and Torres Strait Islander people, representing 3.7% of all cases (418,311/11,291,678) in the Omicron wave to date.

a 'ICU' and 'died' are not mutually exclusive categories; 'died' can include cases who died with or without prior admission to ICU. Therefore, the number of cases admitted to ICU or having died will not equal the sum of cases in ICU or died.

b Rate per 100,000 population for the given time period. Aboriginal and Torres Strait Islander population data is based on the Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at 2021.

Of the COVID-19 cases notified among Aboriginal and Torres Strait Islander people from 15 December 2021 to date, and where location of residence was known, 54.9% (228,214/415,530) lived in a regional or remote area (Table 3). Most cases reported in outer regional and remote areas since the start of the Omicron wave were diagnosed by rapid antigen test (RAT), at 71.4% (55,044/77,069) and 72.4% (37,247/51,446), respectively. It should be noted that the reliance on RATs for diagnosing COVID-19 is greater in regional and remote areas than in major cities, resulting in a larger under-representation of cases in regional and remote areas than in major cities, due to the changes in reporting requirements of positive RATs.

Nationally, there have been 404 COVID-19 associated deaths reported in Aboriginal and Torres Strait Islander people from the start of

the pandemic to 2 July 2023 (Table 4). This comprises 133 from New South Wales; 125 from Queensland; 55 from the Northern Territory; 48 from Western Australia; 24 from South Australia; 15 from Victoria; and two each from the Australian Capital Territory and Tasmania. Additionally, 678 Aboriginal and Torres Strait Islander cases have been admitted to intensive care units (ICU) nationally. Since the start of the fifth Omicron wave, the notification rate, to NNDSS, of severe cases (measured as those who were admitted to ICU or died) in Aboriginal and Torres Strait Islander people is 9.0 per 100,000 population, compared to 13.0 per 100,000 population during the fourth wave and 19.7 per 100,000 population during the third wave (Table 4). It should be noted that ICU status in NNDSS is likely incomplete.

Figure 3: COVID-19 cases, deaths and ICU admissions, Australia, by date of onset, Australia, 27 June 2022 to 2 July 2023^{a,b}

- a Source: NNDSS extract from 19 July 2023 for cases with an illness onset from 27 June 2022 to 2 July 2023.
- b The shaded bars at the right represent the most recent two reporting weeks and should be interpreted with caution, as cases with an illness onset in these weeks may not have yet developed severe disease.

Severity

(NNDSS, FluCAN, SPRINT-SARI)

Given the delay between illness onset and severe illness, and to provide a more accurate assessment of severity, cases with an onset in the last two weeks of the reporting period have been excluded from analyses on the weekly rate of cases with severe illness (defined as cases admitted to ICU or died) and on the proportion of cases admitted to ICU or died.

Following the emergence of the Omicron variant, the number of cases with severe illness peaked in mid-January 2022, at approximately 1,200 severe cases per week (not depicted). Since this time there have been subsequent smaller peaks in severe illness, in the week ending 24 July 2022 at 899 severe cases per week and week ending 18 December 2022 at 487 severe cases per week. Since the start of the fifth Omicron wave, the number of cases with severe illness increased to over 290 severe cases per week in the week ending 28 May 2023 (Figure 3).

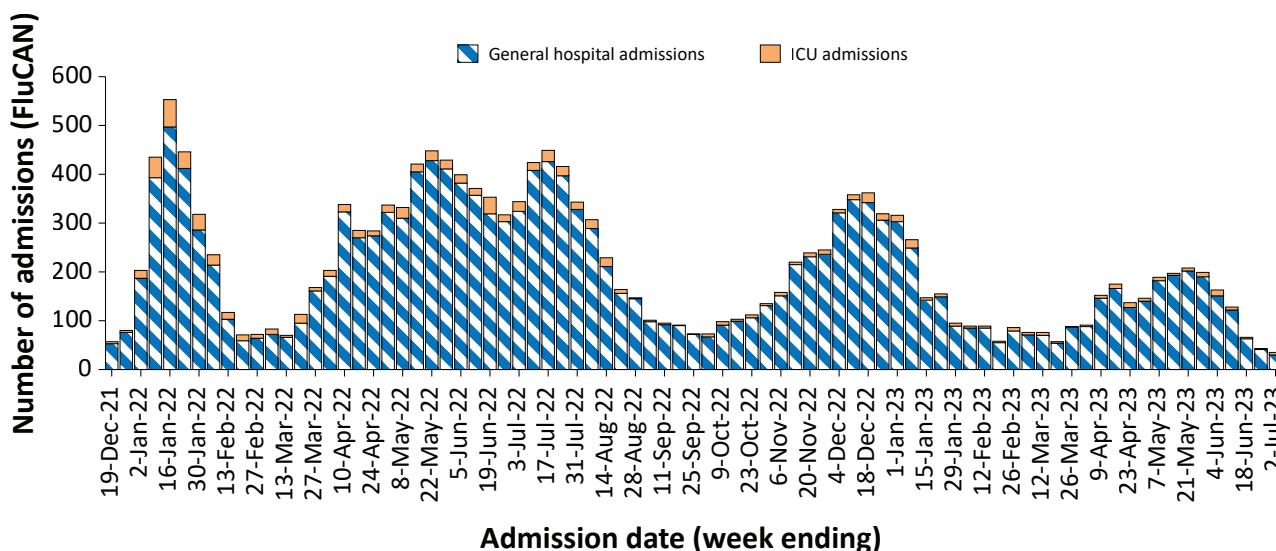

Rates of severe illness continue to be greater in older age groups, with the highest rates among those aged 60 years and older (Figure 4). Among this age group, there have been three notable peaks in severe illness since the emergence of Omicron: in the week ending 16 January 2022 (17.2 cases per 100,000 population; not depicted), in the week ending 24 July 2022 (13.4 cases per 100,000 population) and in the week ending 18 December 2022 (7.2 cases per 100,000 population). From the start of the fifth Omicron wave to the week ending 2 July 2023, the highest rate of severe illness among those aged 60 years and older was observed in the week ending 28 May 2023 at 4.5 cases per 100,000 population. In comparison, rates of severe illness in younger age groups have remained relatively low and stable throughout the Omicron waves, not surpassing three cases per 100,000 population per week over that period (Figure 4).

Figure 4: Age-specific rates of COVID-19 cases admitted to ICU or died, by date of onset, Australia, 27 June 2022 to 18 June 2023^{a,b,c}

- a Source: NNDSS extract from 19 July 2023 for cases with an illness onset from 27 June 2022 to 18 June 2023; cases with an illness onset in the last two weeks (27 March–2 July 2023) were excluded to account for the delay between onset and development of severe illness.
- b Population data based on Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at June 2022.
- c Inset graph displays trends of age groups aged < 60 years.

Hospitalisation and ICU admissions

Influenza Complications Alert Network—FluCAN

Between 15 December 2021 and 2 July 2023, there were 16,175 hospital admissions with confirmed COVID-19 reported at Influenza Complications Alert Network (FluCAN)

sentinel sites, including 5.4% (926/16,998) admitted directly to ICU (Figure 5). During the four-week reporting period (5 June – 2 July 2023) there were 272 admissions with COVID-19 reported at FluCAN sentinel sites, with 5.9% (16/272) admitted directly to ICU.

Table 5: Patient outcomes for adult COVID-19 cases (aged greater than or equal to 18 years), admitted to ICUs participating in the sentinel surveillance system, Short Period Incidence Study of Severe Acute Respiratory Infection (SPRINT-SARI), Australia, 15 December 2021 – 2 July 2023^a

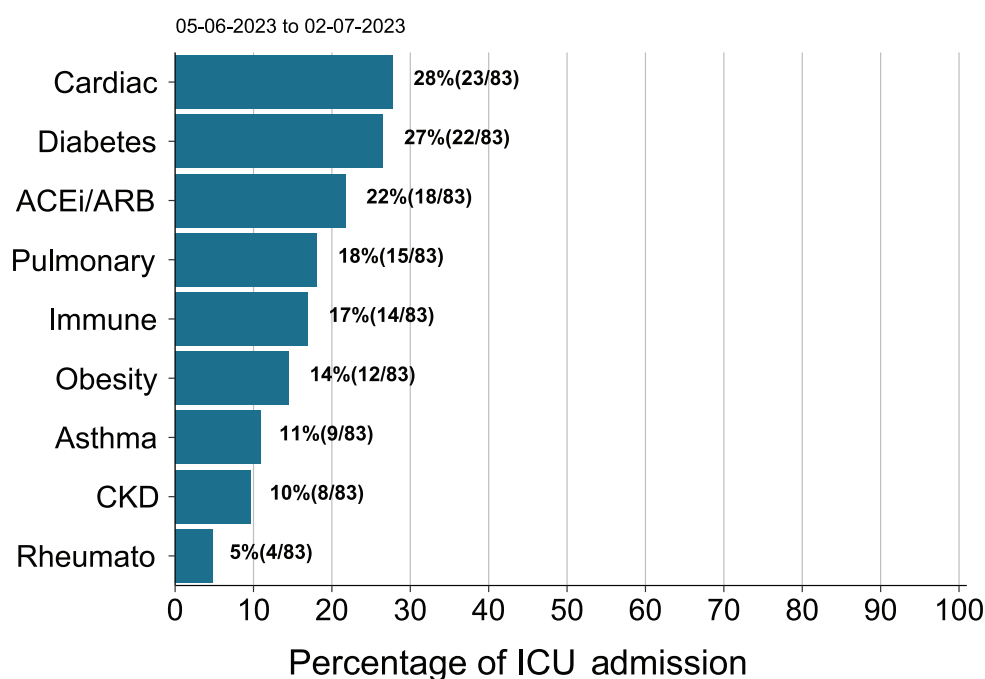

Outcomes	Current reporting period 5 June – 2 July 2023 (n = 83)	Omicron wave to date 15 December 2021 – 2 July 2023 (n = 5,647)
Patient status		
Ongoing care in ICU	25 (30.1%)	56 (1.0%)
Ongoing care in hospital ward ^b	25 (30.1%)	92 (1.6%)
Transfer to other hospital/facility	0 (0%)	353 (6.3%)
Transfer to rehabilitation	0 (0%)	539 (9.5%)
Discharged home	26 (31.3%)	3463 (61.3%)
Mortality - ICU	4 (4.8%)	745 (13.2%)
Mortality - hospital ward	3 (3.6%)	300 (5.3%)
Unknown	7 (8.4%)	1045 (18.5%)
Missing ^c	0 (0%)	76 (1.3%)

a Source: SPRINT-SARI.⁵

b Patients who were admitted in ICU/hospital wards with no discharge information for less than 90 days were assumed to have ongoing care in the hospital.

c Patients who were admitted to ICU/hospital wards for more than 90 days with no discharge information were treated as “missing data”.

Figure 6: Prevalence of comorbidities for COVID-19 cases among admitted adult ICU patients (aged greater than or equal to 18 years), at participating SPRINT-SARI sites, Australia, 5 June – 2 July 2023^{a,b}

a Source: SPRINT-SARI. Only includes adult cases (≥ 18 years old) and excludes those with missing data on comorbidities or where comorbidity is unknown.

b Abbreviated comorbidities defined as: Cardiac: chronic cardiac disease; ACEi/ARB: past use of ACE inhibitor or A2 Blocker; CKD: chronic kidney disease; Pulmonary: chronic pulmonary disease (not including asthma); Immune: chronic immunosuppression; and Rheumato: rheumatologic disorder.

Since the start of the fifth Omicron wave (1 March 2023), for patients admitted to FluCAN sentinel sites with confirmed COVID-19, the median length of stay was four days (interquartile range, IQR: 2–8 days). This is comparable with the median length of stay observed during the third (three days; IQR: 2–7 days) and fourth Omicron waves (three days; IQR: 2–7 days).

Since the start of the fifth Omicron wave (1 March 2023), there have been 2,212 patients with confirmed COVID-19 admitted to FluCAN sentinel sites, with weekly admissions peaking in the week ending 21 May 2023 (n = 208) (Figure 5). Of the patients admitted during the fifth Omicron wave, 34.1% (753/2,212) were children (< 16 years). Note that hospital admissions in children under 16 years of age are over-represented in the FluCAN data to provide increased information on this at-risk population. The age distribution of hospital admissions in the FluCAN surveillance system may not reflect the age distribution of all COVID-19 admissions nationally.

Short Period Incidence Study of Severe Acute Respiratory Infection—SPRINT-SARI

Between 15 December 2021 and 2 July 2023, there were 5,647 COVID-19 cases admitted to ICUs participating in the sentinel surveillance system—Short Period Incidence Study of Severe Acute Respiratory Infection (SPRINT-SARI)⁵ (Table 5). During this time, 61.3% (3,463/5,647) of patients were discharged home, 13.2% (745/5,647) died in ICU and 5.3% (300/5,647) died within the general hospital ward, with an overall in-hospital mortality rate of 18.5% (1,045/5,647) for COVID-19 cases admitted to ICUs.

In the four-week reporting period (5 June – 2 July 2023), there were 83 adult patients (43 males, 40 females; median age: 63 years; interquartile range: 55.5–74 years) with COVID-19 admitted to ICU reported at SPRINT-SARI sentinel sites (Table 5).

Since the start of the Omicron wave (15 December 2021) to 2 July 2023, for patients admitted to SPRINT-SARI sentinel sites with COVID-19 (n = 5,647), the median length of stay in ICU was 3.4 days (range: 0–88.9 days), the median length of stay in hospital was 10.9 days (range: 0.1–89.2 days) and the median duration of mechanical ventilation was 4.1 days (range: < 0.01–82.0 days).

During the four-week reporting period (5 June – 2 July 2023), for patients admitted to SPRINT-SARI sentinel sites with COVID-19 (n = 83), the median length of stay in ICU was 3.4 days (range: 0.3–17.7 days), the median length of stay in hospital was 6.5 days (range: 0.5–35.8 days) and the median duration of mechanical ventilation was 3.4 days (range: 0.4–13.0 days).

Risk factors for severe disease

Comorbidity data extracted from SPRINT-SARI reflect the sickest patients with COVID-19 who are managed in ICU; data are therefore not generalisable to all cases. In adult patients admitted to ICU with COVID-19 between 5 June and 2 July 2023, where comorbidity information was available, the most prevalent comorbidities were chronic cardiac disease (27.8%) followed by diabetes (26.5%) and past use of an angiotensin-converting enzyme (ACE) inhibitor or alpha-2 (A2) blocker (21.7%) (Figure 6). Of those adult patients admitted to ICU during the four-week reporting period, for whom comorbidity data was known, 41.0% (34/83) of adult ICU patients had three or more comorbidities.

Paediatric Inflammatory Multisystem Syndrome - Temporally Associated with SARS-CoV-2

Paediatric Active Enhanced Disease Surveillance

Since the start of the pandemic to 2 July 2023, there have been 182 cases of paediatric inflammatory multisystem syndrome - temporally associated with SARS-CoV-2 (PIMS-TS) reported to the Paediatric Active Enhanced Disease Surveillance network (PAEDS), with three new cases reported in the last four weeks, two new cases from the previous reporting period and a total of 16 cases reported since the start of 2023 (Figure 7). The majority of PIMS-TS cases to date have occurred in those aged 5 to < 12 years (52%; 95/182), followed by those aged 6 months to < 5 years (27%; 50/182). To date, there have been no PIMS-TS associated deaths.

COVID-19 deaths

From the start of the fifth Omicron wave (1 March 2023) to the week ending 2 July 2023, there have been 2,447 COVID-19-associated deaths notified. In total, there have been 22,286 COVID-19-associated deaths reported in NNDSS since the start of the pandemic (Table 6). The overall crude case fatality rate from the start of the Omicron wave to date is 0.18%, which is lower than the crude case fatality rate for the Delta wave (0.71%) (Table 7).

Table 7: COVID-19 associated case fatality rates among cases notified to NNDSS, by age group and date of onset, 1 January 2020 to 18 June 2023^{a,b,c,d}

Age group (years)	Omicron to date 15 December 2021 – 18 June 2023	Delta 16 June – 14 December 2021	Pandemic to date 1 January 2020 – 18 June 2023
0–9	< 0.05%	< 0.05%	< 0.05%
10–19	< 0.05%	< 0.05%	< 0.05%

Australia	0.18%	0.71%	0.19%

a Source: NNDSS, extract from 19 July 2023 for deaths with an illness onset date to 18 June 2023.

b To account for the lag between illness onset and the development of severe illness, cases with an onset date in the last two weeks have been excluded from calculations of the case fatality rate.

c A value of 0.00% indicates that no COVID-19 associated fatalities occurred during the indicated period for the specified age group.

d Crude case fatality rates which reflect number of deaths as a proportion of reported COVID-19 cases during specific periods, noting these rates are likely overestimated due to underreporting of cases.

Table 8: Australian SARS-CoV-2 genome sequences and proportion of positive cases sequenced, 5 June – 2 July 2023 and cumulative to date ^{a, b, c, d}

Measure	Reporting period 5 June – 2 July 2023	Cumulative 23 January 2020 – 2 July 2023
SARS-CoV-2 cases sequenced ^a	4,431	202,807
Percentage of positive cases sequenced ^b	11.0%	3.1%

- a Based on individual jurisdictional reports of sequences and case numbers. Calculations of the percentage of cases sequenced based on the number of sequences available in AusTrakka may not always be up to date, since this may include duplicate samples from cases and may not represent all available sequence data.
- b Total SARS-CoV-2 case numbers as reported by jurisdictional laboratories based on PCR results only. Cases identified via rapid antigen testing are reported differently by each jurisdiction and cannot be followed up for sequencing. They are therefore not included in the sequencing proportions reported here. Sequencing of samples from cases identified in the reporting period may be in process at the time of reporting. Remaining unsequenced samples may be due to jurisdictional sequencing strategy, or where samples have been deemed unsuitable for sequencing (typically because viral loads were too low for sequencing to be successful).
- c Changes to reporting of case numbers in some jurisdictions have impacted the ability of laboratories to calculate proportion of sequenced case numbers for specified reporting periods.
- d Data from the Australian Capital Territory and the Northern Territory were not available for this reporting period.

Genomic surveillance and virology

(Communicable Disease Genomics Network, AusTrakka and jurisdictional sequencing laboratories)

Nationally, 3.1% of COVID-19 cases have been sequenced since the start of the pandemic in January 2020, based on jurisdictional reporting (Table 8). Case numbers and sequencing proportion are primarily based on polymerase chain reaction (PCR) results only, as rapid antigen tests do not allow for sequencing. However, some jurisdictions currently include both PCR and RAT positive tests in case numbers. Where jurisdictions are unable to separate PCR confirmed and RAT only cases, proportions are an estimate only. Since late 2022, referrals of positive PCR samples to sequencing laboratories have decreased significantly, resulting in changes to sequencing strategies across the country. Changes to sequencing strategies and availability of testing may cause these proportions to fluctuate over the coming months.

Variants of concern (VOC)

AusTrakka⁶ is actively monitoring and reporting on one lineage and its associated sub- and sub-sub-lineages, currently designated as a Variant of Concern (VOC) by international organisations, including the World Health Organisation: Omicron (B.1.1.529). The Omicron variant displays a characteristic set of mutations, including several variations in the genomic region encoding the spike protein thought to have the potential to increase transmissibility and/or immune evasion.^{7,8} Further information on variants is available in the Technical Supplement.²

Unlike previous periods in Australia's COVID-19 waves, where one or two dominant lineages were the main driver of disease, there is currently significant diversity in the range of sub-sub-lineages circulating within Australia. During this reporting period, more than 200 unique lineages have been identified, and it is likely that there are more that are not being characterised through whole genome sequencing. This diversity of circulating lineages has sometimes been referred to as a 'variant soup'. Many of these circulating lineages will die out without causing a significant disease burden, but others appear to have stronger growth potential.

Figure 8: Omicron sub-lineage proportions in Australia since 1 January 2023 by sample collection date ^{a,b,c}

- a Sequences in AusTrakka; aggregated by week.
- b The current reporting period (5 June to 2 July 2023) is marked by the dashed lines.
- c Proportions in the figure may not be representative when sequence numbers are small. Data may change week-to-week as sequences with older collection dates are uploaded. These numbers are not equivalent to number of cases, as there may be duplicates in the AusTrakka data. Newly designated Omicron sub-lineages have been collapsed into parent lineages BA.1, BA.2 (except BA.2.75, displayed separately), BA.3, BA.4 and BA.5; recombinants are designated by X*.

Currently CH.1.1 (BA.2.75 sub-lineages) and XBB* sub-lineages (recombinant of BJ.1 [BA.2.10] and BM.1.1.1 [BA.2.75.3]), including XBB.1.5, XBB.1.16 and XBB.1.9.1 and XBB.1.9.2), and XBC (recombinant of Delta (B.1.617.2) and Omicron (B.1.1.529)), have emerged with strong signals both within and across different jurisdictions. All sub-lineages and recombinants are being monitored by AusTrakka and the CDGN VOC Working Group due to their increasing prevalence.

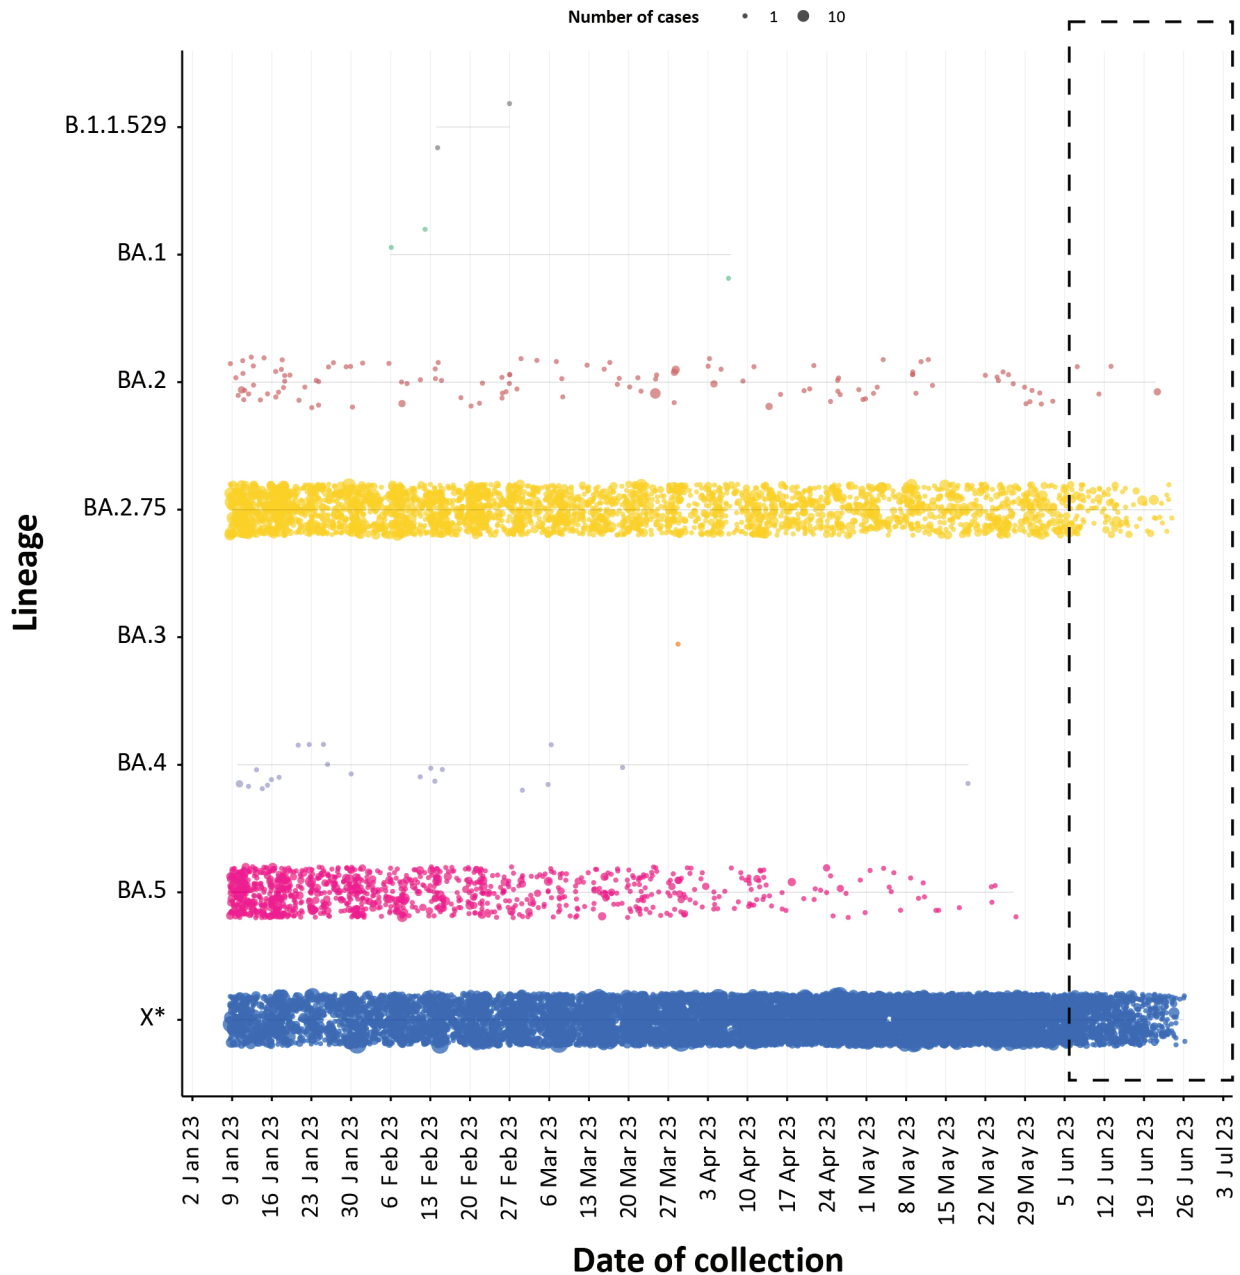

AusTrakka sub-lineage breakdown

From 5 June to 2 July 2023, there were 1,314 sequences uploaded to AusTrakka, with the most recent collection date of 12 June 2023. Almost all sequences uploaded during this reporting period have been assigned to sub-lineages within B.1.1.529 (Omicron) or to recombinants consisting of two Omicron sub-lineages. There have been five major sub-lineages defined under B.1.1.529: BA.1, BA.2, BA.3, BA.4 and BA.5,

and a large number of sub-lineages, including recombinants, under these; all are designated Omicron.

Of the 1,314 sequences uploaded to AusTrakka in the last four weeks, most (88.5%; 1,163/1,314) were recombinant or recombinant sub-lineages and 11.5% (151/1,314) were BA.2 sub-sub-lineages. All BA.2 sequences (n = 151) identified in the reporting period belonged to BA.2.75 sub-lineages (specifically the CH.1.1 sub-lineage within BA.2.75). No BA.1, BA.3, BA.4 or BA.5 sequences were identified within this period. The predominant recombinant lineages sequenced in this period are XBB*, with other newly emergent recombinants currently only accounting for a minority.

Figure 9: Samples in AusTrakka since 2 January 2023 (past 26 weeks), by lineage and date of collection ^{a,b}

- a The current reporting period (5 June to 2 July 2023) is marked by the dashed lines. The size of each dot is proportional to the number of sequences observed in each jurisdiction each day.
- b Newly designated Omicron sub-lineages have been collapsed into parent lineages BA.1, BA.2 (except BA.2.75, displayed separately), BA.3, BA.4 and BA.5; recombinants are designated by X*.

The sub-lineage breakdown of all Omicron sequences uploaded to AusTrakka since first identification in November 2021, to date: 17.0% (n = 26,251) are BA.1; 26.9% (n = 41,528) are BA.2 (excluding BA.2.75); 9.0% (n = 13,864) are BA.2.75; < 0.1% (n = 3) are BA.3; 3.3% (n = 5,052) are BA.4; 27.9% (n = 43,117) are BA.5;

recombinants account for 16.0% (n = 24,898) of all Omicron sequences to date. All sub-sub-lineages have been collapsed into respective major sub-lineages.

Figure 10: Weekly trends in fever and cough amongst FluTracking survey participants (age-standardised) compared to the average of the previous five years, Australia, 1 January 2020 – 2 July 2023^a

^a In years prior to 2020, FluTracking was activated during the main Influenza season from May to October. A historical average beyond the week ending 11 October is therefore not available. In 2020, FluTracking commenced ten weeks early to capture data for COVID-19.

Acute respiratory illness (FluTracking, ASPREN)

Based on self-reported FluTracking data,⁹ there has been an overall increase in the prevalence of respiratory illness, ‘fever and cough’ and ‘runny nose and sore throat’ symptoms, in the community since late January 2023. Over the current period, the rate of ‘fever and cough’ has decreased from a peak of 2.4% to 1.7% of survey participants, while remaining lower than the rates observed during the same period in 2022 (Figure 10). In the current reporting period, the rate of ‘runny nose and sore throat’ symptoms has continued to increase into early July 2023, following a slight decrease at the start of June 2023. The rate of ‘runny nose and sore throat’ symptoms is now similar to that observed in 2022 for the same period (Figure 11).

Over the reporting period, FluTracking data indicated that 10.5% of participants with ‘fever and cough’ were tested for SARS-CoV-2 with a PCR test and 74.4% were tested using a RAT (noting that in some instances RATs will be followed up by a PCR test for the same case). Of those with ‘runny nose and sore throat’, 2.9% were tested for SARS-CoV-2 using a PCR test and 52.6% were tested using a RAT. In the current reporting period, the percent positivity for ‘fever and cough’ symptoms decreased for PCR (10.8%) and for RAT (22.9%) compared to the previous reporting period. For ‘runny nose and sore throat’ symptoms, the percent positivity decreased for both PCR and RAT to 2.1% and 4.5%, respectively. Note that participants with one set of symptoms are not excluded from having the other. It is important to acknowledge that there may be legitimate reasons why people did not get tested, including barriers

Figure 11: Weekly trends in runny nose and sore throat amongst FluTracking survey participants (age-standardised), Australia, 29 March 2020 – 2 July 2023^a

a Data on runny nose and sore throat were only collected systematically after 29 March 2020, therefore a historical average for this symptom profile is unavailable.

to accessing testing. Symptoms reported to FluTracking are not specific to COVID-19 and may also be due to infections with other respiratory pathogens and to chronic diseases, such as asthma.

Since the start of 2023 to 2 July 2023, of those presenting to sentinel ASPREN sites with influenza-like illness who were tested for respiratory viruses, 64.9% (385/593) tested positive, an increase of 2.0% compared with the previous four-week period. Among those positive, the most common viruses detected were rhinovirus (28.6%; 72/385), followed by influenza A (24.2%; 93/385), SARS-CoV-2 (16.1%; 62/385) and influenza B (10.9%; 42/385).

Countries and territories in Australia's near region

According to WHO, countries and territories in the South-East Asia and Western Pacific regions reported 613,455 new cases and 1,188 deaths in the four-week period to 2 July 2023.¹⁰ Compared with the previous four-week reporting period, new cases and deaths decreased in both the South-East Asia (change in cases: -69%; change in deaths: -55%) and the Western Pacific regions (change in cases: -36%; change in deaths: -41%).¹⁰ In total, since the start of the pandemic, over 265 million cases and 1.2 million deaths have been reported in the two regions.¹⁰

In the four-week period 5 June to 2 July 2023, selected countries with the greatest changes in COVID-19 cases and deaths are highlighted in the South-East Asia and the Western Pacific regions (Table 9). In the previous four weeks, at the country level, the highest numbers of new

Table 9: Cumulative cases and deaths, and new cases and deaths reported in the four-week period to 2 July 2023 for selected countries in Australia’s near region according to WHO ^{a,b}

Country	Cumulative cases	New cases reported in the last 4 weeks	Change in new cases in the last 4 weeks ^b	Cumulative deaths	New deaths reported in the last 4 weeks	Change in new deaths in the last 4 weeks ^b

b Percent change in the number of newly confirmed cases/deaths in the most recent four-week period compared to the four weeks prior.

cases were reported from the Republic of Korea (n = 383,767) and Australia (n = 85,167), with the highest proportional increase observed in Bangladesh (3,063 vs 1,301 new cases; +135%) (Table 9). During the four-week reporting period, the highest number of new deaths were reported from Australia (n = 241) and China (n = 229), followed by Thailand (n=208).

As of 2 July 2023, over 767 million COVID-19 cases and over 6.9 million deaths have been reported globally since the start of the pandemic, with a global case fatality rate (CFR) of approximately 0.91%. The two regions reporting the largest burden of disease over the past four weeks were the Western Pacific (67% of total cases) and Europe (17% of total cases).¹⁰
